

$$S = \{ A \mid A \text{ is a set and } A \notin A \}$$

$S \in S?$

The halting problem:

There is no computer algorithm that will accept as input any algorithm  $X$  and data set  $D$  and then outputs "halts" or "loops forever" to indicate whether  $X$  terminates in a finite number of steps when  $X$  is run w/  $D$  as input.

## Proof (by contradiction)

Suppose there is such an algorithm  $\text{CheckHalt}(X, D)$

$\text{CheckHalt}(X, D)$  prints  
"halts" if  $X$  terminates  
on input  $D$  in  
finite # of steps

"loops forever" if  $X$  does not  
terminate on  $D$

Note: we can run  $\text{CheckHalt}(X, X)$

---

Define a second algorithm  
 $\text{Test}(X)$  where  $X$  is a program

$\text{Test}(X)$ : call  $\text{CheckHalt}(X, X)$

~~output:~~

loops forever; iff  $\text{CheckHalt}(X, X)$   
prints "halts"

halts; iff  $\text{CheckHalt}(X, X)$   
prints "loops forever"

---

now run  $\text{Test}(\text{Test})$

if  $\text{Test}(\text{Test})$  terminates  
then  $\text{CheckHalt}(\text{Test}, \text{Test})$   
printed "Loops forever"  
meaning  $\text{Test}(\text{Test})$  looped  
forever

if  $\text{Test}(\text{Test})$  loops forever  
then  $\text{CheckHalt}(\text{Test}, \text{Test})$   
printed "halts"  
indicating that  $\text{Test}(\text{Test})$   
terminates.

which are contradictions  
Since  $\text{Test}$  follows from  
the def. of  $\text{CheckHalt}$ ,  
 $\text{CheckHalt}$  cannot exist.

## Ch. 6: Counting and Probability

a random process:

- one outcome from a set of outcomes
- impossible to say w/ certainty which will occur.

---

sample space: set of all possible outcomes of a random process.

event: subset of the sample space

If  $S$  is a finite sample space  
in which all outcomes are  
equally likely and  $E$  is some  
event in  $S$

The probability of  $E$ ,  $P(E)$

$$P(E) = \frac{\text{the number of outcomes in } E}{\text{the total \# of outcomes in } S}$$
